

ii) Thought-provoking Question: If you finally find the dataset of any event/experiment that you've been searching for (say in .csv format), do you think your job of analysing the data is done, just by performing operations (which we will learn) on the computer? Are there any issues you could face ? Give ideas. Possibly you come up with some new ones! (I don't expect perfect answers of course; Put the PDF of your answer in the GitHub repo.)

Ans)

Yes, I think the job should be done after I find the dataset because the operations and techniques which we will be learning/ which are available would be those which are specifically designed for analysing this type of data.

Of course, some problems could arise in the form of insufficient data or in the form of the dataset exceeding the computing power of the algorithm or the device. A definite judgement on my part can only be made after I learn what is to be learnt in this regard.
